I have provided you with a fully functioning script that provides 2 windows. 1 can be used to enter data and the other to view it. Before reading the code I want you to run it, see how it acts when using it. Then close and rerun to see if it acts any differently. After running through and seeing how it acts then you should read through the code to see what is happening and how it works.

Your assignment is to do something very similar. You will have a script that shows a single window. The script will get the average of the numbers entered. You will need one entry box that takes input(numbers only), a button that adds the number to a list, a button that says calculate. The entry box should be colored red when bad data is entered. When the calculate button is pressed the average should be calculated printed as a text in the window then the list should be cleared to be able to run again.
